We demonstrate that the introduction of a subwavelength periodic modulation into a metallic structure strongly modifies the guiding characteristics of the surface plasmon polariton (SPP) modes supported by the system [1]. Moreover, it is also shown how a periodic corrugation could even create a new type of SPP-type mode, a domino plasmon polariton (DPP), Fig.1, in a structure that does not support surface plasmons in the non-corrugated configuration. We present a totally new design for surface plasmon polariton waveguides based on DPP for terahertz applications, which is easy to fabricate [2]. These waveguides are likely to enable interesting device applications stemming from their unique properties: a dispersion that is nearly insensitive to the waveguides' width, a nearly flat power distribution within the waveguide, an excellent field confinement factor, and reasonable loss figures.
