Abstract

In this study, silver doped and silver decorated TiO\textsubscript{2} thin films were prepared by sol-gel dip-coating method. Silver nitrate was dissolved in the TiO\textsubscript{2} sol to obtain Ag-doped samples with different dopant concentration. The silver decorated TiO\textsubscript{2} samples were prepared by dip-coating pure TiO\textsubscript{2} thin film in AgNO\textsubscript{3} aqueous solution. Thermal decomposition of AgNO\textsubscript{3} at 414 °C was the idea to prepare silver decorated TiO\textsubscript{2} thin films and coated samples were annealed at different temperatures. The structure and composition of prepared samples were characterized by X-Ray diffraction (XRD) and X-Ray photoelectron spectroscopy (XPS). The optical transmission spectra of the samples were measured using UV-Vis spectroscopy. The refractive index of thin films was recorded by NKD. The optical band gap was calculated using Tauc plot (variation of (\(\alpha h\nu\))\textsuperscript{0.5} with \(h\nu\)), obtained from the absorption spectra of the samples. Surprisingly, it was observed that silver cations were reduced to metallic silver in sample which was annealed at 120 °C [1]. The high band gap value of pure and silver doped TiO\textsubscript{2} thin films are attributed to thermal stress effects produced in the films [2-5].
