ESQC-STM

Elastic Scattering Quantum Chemistry

Developed by C. Joachim and P. Sautet in 80'

Tunnelling of an electron: scattering event ~~gap: defect~~

Method models the tip-adsorbate-substrate system by a mono-electronic Hamiltonian (computed using Extended Hückel method)

Matrix representation: within the tight-binding approximation

Complete chemical description of the tip, adsorbate, surface

Full geometry of the tip, adsorbate, surface

Transmission coefficient *t(E)*

$$t = |\tau|^2 = \frac{1}{|F|^2} = \frac{1}{|\underline{\underline{T}}_{11}|^2}$$

Generalised Landauer formula

$$\frac{I}{V} = \frac{e^2}{\pi\hbar} t(E_F).$$

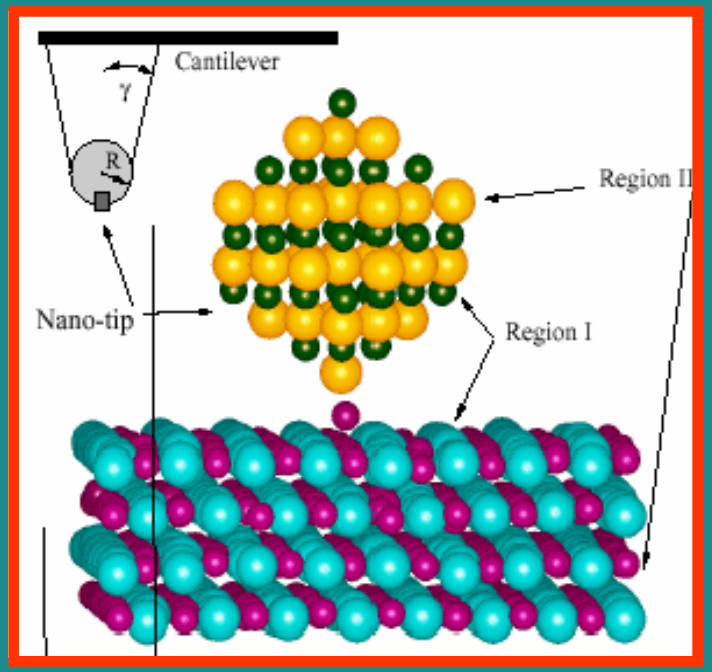
AFM imaging

Extensive calculations are required to determine the 3D force-field for the moving tip - usually interatomic potentials for surface-molecule-tip interaction are needed.

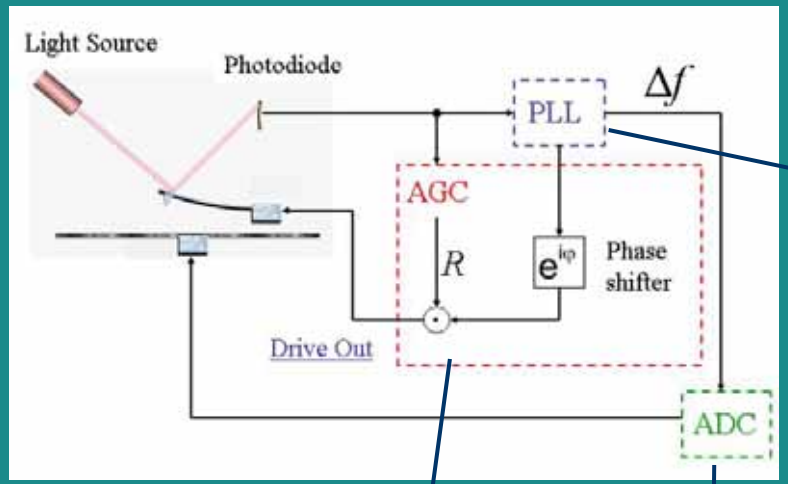
Frequency shift as a function of closest approach and lateral position is then calculated.



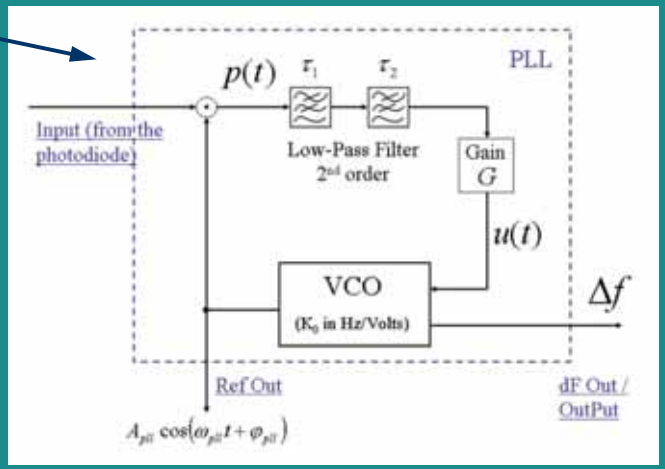
It is assumed that the instrumentation works ideally, the tip trajectory is periodic and that the tip-surface interaction is **conservative**

Imaging weakly adsorbed atoms and molecules presents new challenges since dynamical processes can occur during the imaging, making image interpretation difficult.

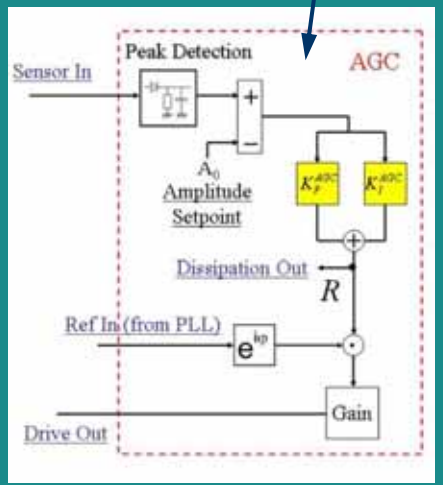
AFM imaging: virtual AFM

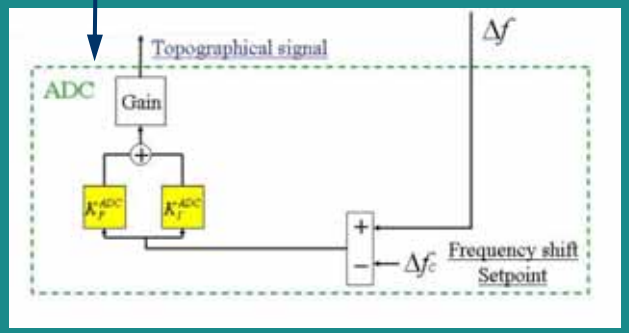


A complete, real time simulation of the entire NC-AFM experiment, including noise.



Developed in a collaboration of **Toulouse** (S. Gauthier), **KCL** (L. Kantorovich) and **UCL** (A. Shluger) groups.





The response of the cantilever and feedback control is realistically accounted for.

It is now possible to investigate and image real-time dynamical processes with a non-conservative tip-surface interaction - such as dissipation, diffusion and manipulation.

Pico-Inside

CEMES

AFM imaging

The following important questions should be addressed:

- **Can we resolve large molecules?**
- **Or, at least, obtain some sub-molecular resolution?**
- **Can we, at the same time, resolve the surface?**
- **And thus position the molecule correctly within the surface?**

These points can be illustrated by the following prototype systems:

C_{60} on the Si(001) surface

Defects on the MgO(001) surface

Pico-Inside

CEMES

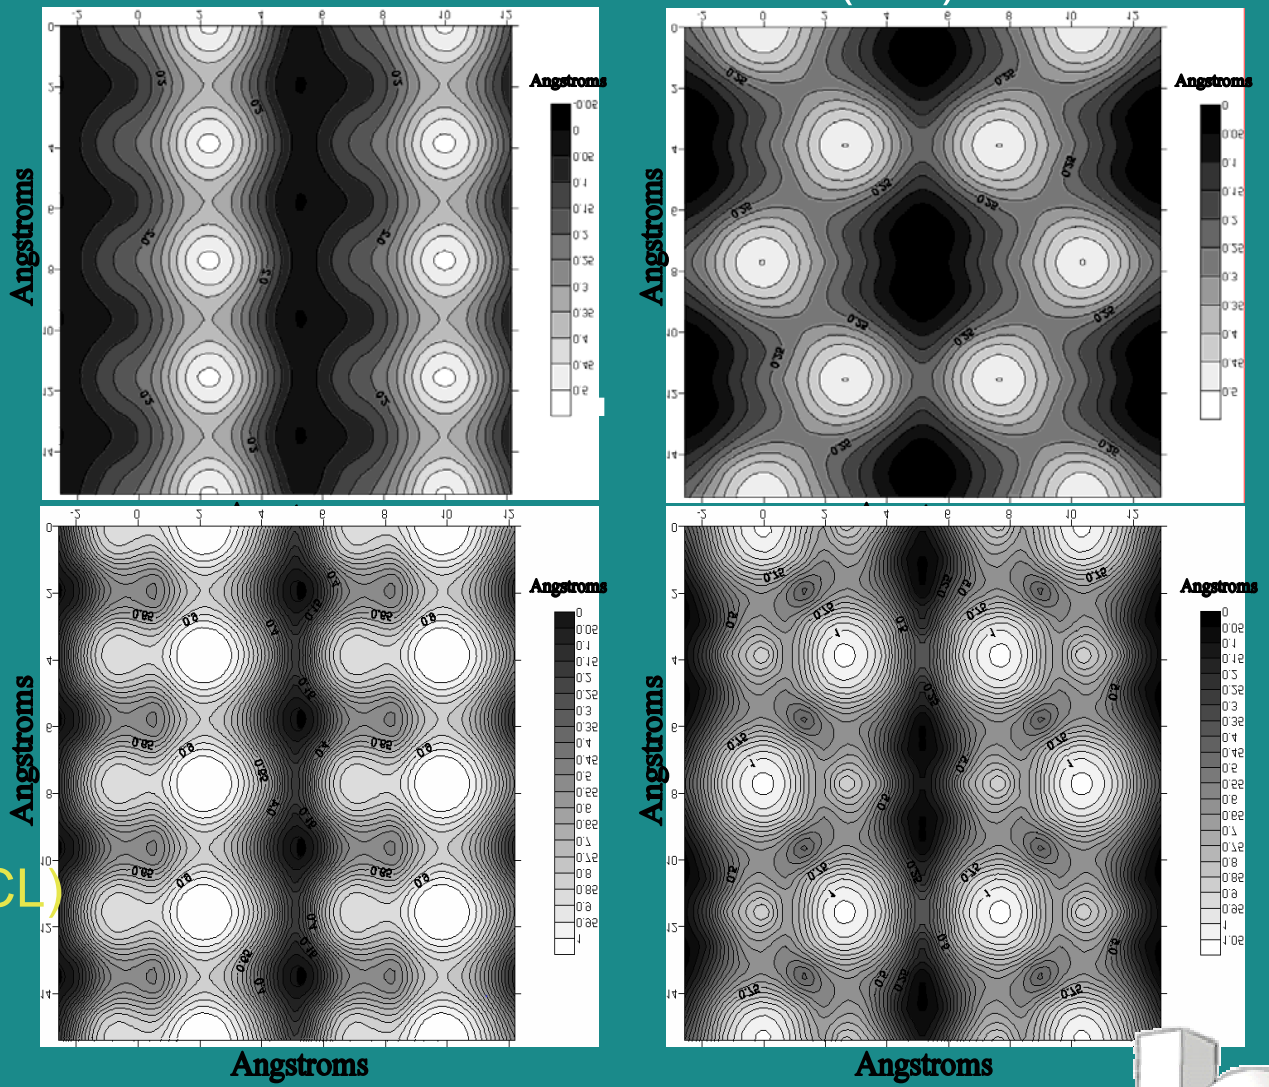
AFM imaging

Si(001) surface: both reconstructions are clearly recognised!

p(2x1) c(4x2)

Small frequency shift

Larger frequency shift



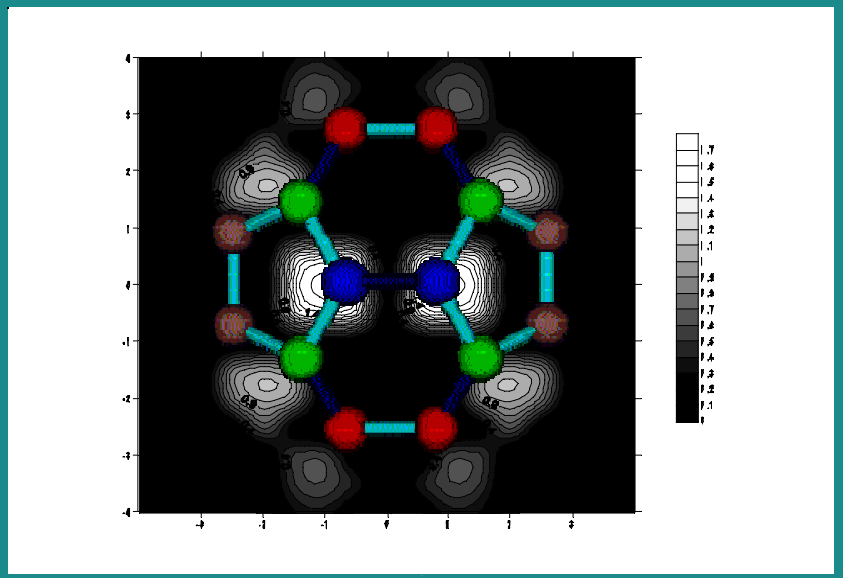
L. Kantorovich (KCL)

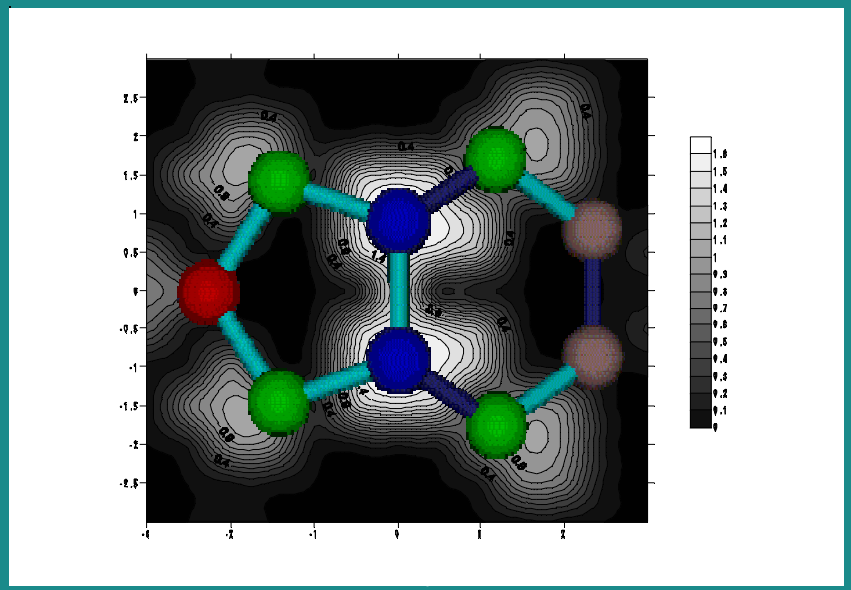
Pico-Inside

CEMES

AFM imaging

C_{60} molecule: pentagons and hexagons can be seen!





- The same frequency shift can be used as for the Si(001) surface
- Therefore, both the molecule and the surface can be recognised
- Thus, as we know all possible adsorbed sites, we should be able to identify the particular configuration the molecules have in the NC-AFM images

L. Kantorovich (KCL)

Pico-Inside

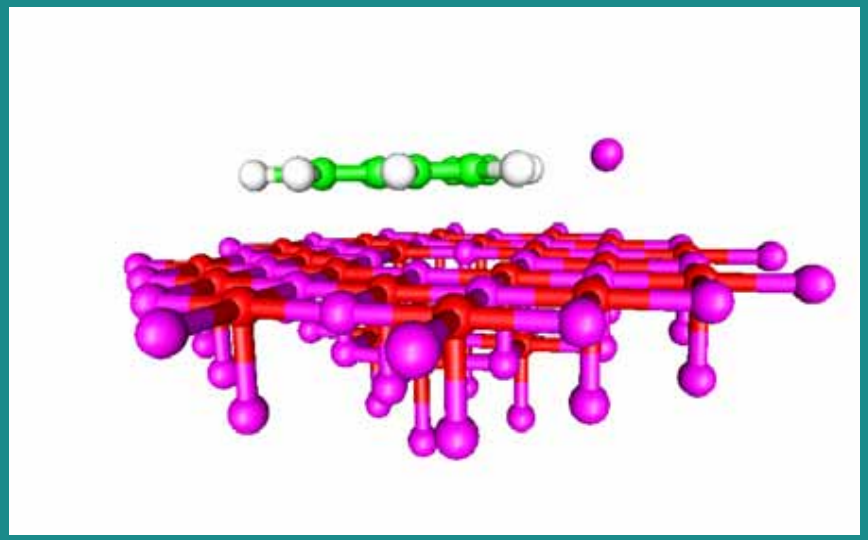
M4nano – Madrid - 4th dec. 2006

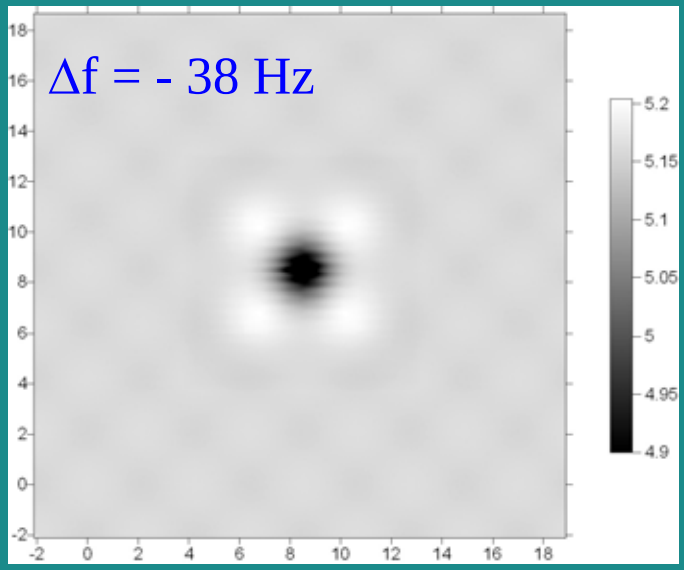
CEMES

AFM imaging

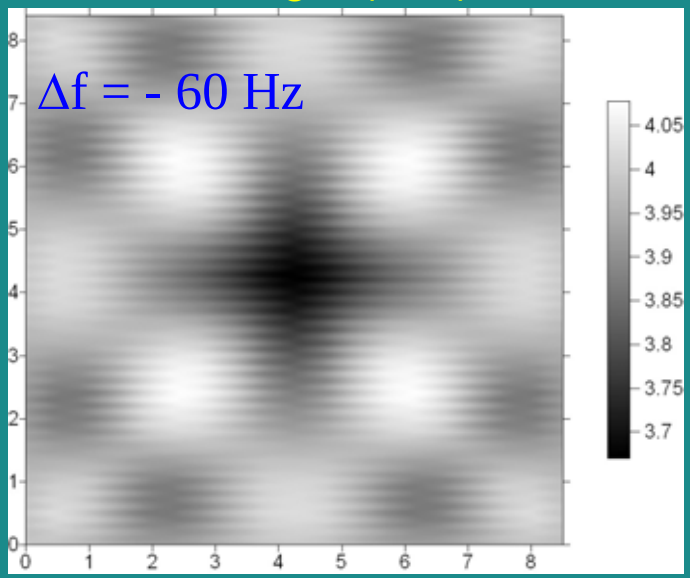
Defects on the MgO (001) surface

The electronic structure of a molecule adsorbed on the MgO surface can be modified by a +2 oxygen vacancy.





Pd on MgO (001)



+2 oxygen vacancy on MgO (001)

Also, metal atoms and clusters (such as Pd) will be required to form connections to the molecule.

We can image these defects and also (in theory) manipulate them laterally with the NC-AFM

A. Shluger (UCL)

M4nano – Madrid - 4th dec. 2006

Pico-Inside

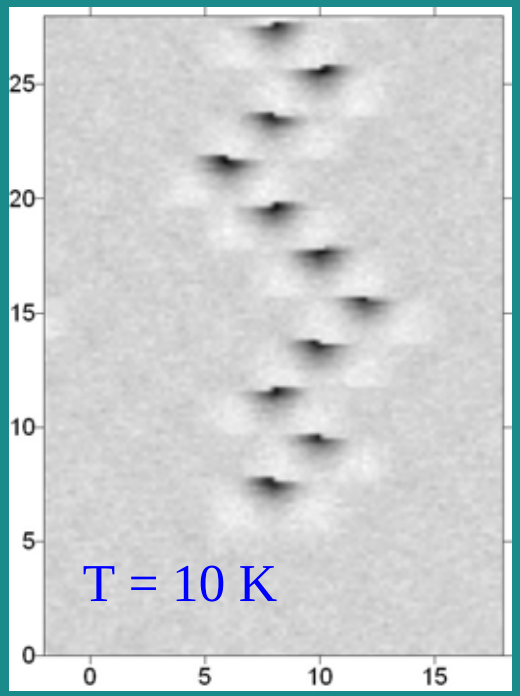
CEMES

AFM imaging

Experimental Noise

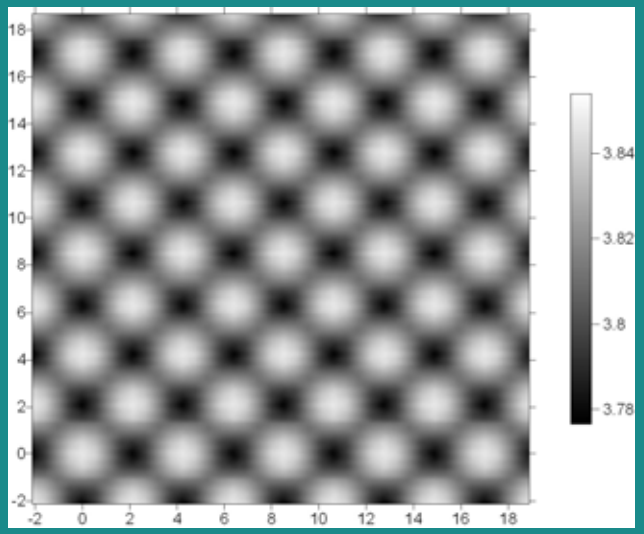
Realistic experimental noise can be added to the virtual instrument:

- Thermomechanical (cantilever) noise
- Photodetector shot noise
- Johnson noise in the electronics

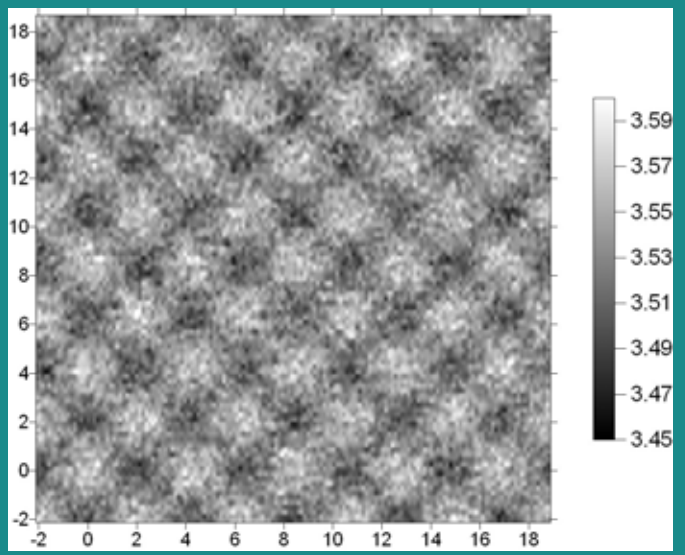


The addition of noise does not remove atomic resolution.

The noise affects the trajectory of the tip, however adatom manipulation is still possible.



MgO(001) - no noise



MgO(001) - with noise at 10 K

Implementation developed through Toulouse, KCL and UCL collaboration

Pico-Inside

CEMES

Conclusion

Exploiting the resources of a single molecule

Understanding the intrinsic mechanisms of a localized action

Controlling the motion of the molecule

Activating the functions for which the molecule has been designed

Necessary coupling of STM calculations and molecular mechanics/molecular dynamics
